

Technical Appendix: Sharpe-ratio variance inflation under cross-sectional and serial dependence in trading panels

Dhananjay S. Chauhan

June 1, 2026

1 Purpose

This appendix contains proof details and secondary empirical artifacts that are omitted from the journal-facing main manuscript for length. The main manuscript is the claim boundary; this appendix is the audit trail for derivations, positive controls, robustness tables, and generated public-data artifacts.

2 Mean-Return Design-Effect Proof

For a selected row model $y_{t,i} = \mu + \lambda_t + \epsilon_{t,i}$ with constant selected count $\bar{n}$, same-date intraclass correlation ρ , and independent dates, the row-pooled mean equals the average of date means:

$$\hat{\mu} = \frac{1}{T\bar{n}} \sum_{t=1}^T \sum_{i=1}^{\bar{n}} y_{t,i} = \frac{1}{T} \sum_{t=1}^T \bar{y}_t.$$

The row-naive variance report is $\sigma^2/(T\bar{n})$. The true one-date variance is

$$\text{Var}(\bar{y}_t) = \frac{1}{\bar{n}^2} \{ \bar{n}\sigma^2 + \bar{n}(\bar{n} - 1)\rho\sigma^2 \} = \frac{\sigma^2}{\bar{n}} \{ 1 + (\bar{n} - 1)\rho \}.$$

Thus

$$\frac{se_{date,true}}{se_{row,naive}} = \sqrt{1 + (\bar{n} - 1)\rho}.$$

This is the Moulton-like design effect used as the mean-return special case in the main text.

3 Sharpe UVIF Derivation

Let R_t be the date-level portfolio excess return and $G_t = (R_t, R_t^2)'$. The annualized Sharpe ratio is the smooth functional

$$f(\mu, m_2) = \sqrt{252} \frac{\mu}{(m_2 - \mu^2)^{1/2}}, \quad d_R = \nabla f(\mu_R, m_{2,R}).$$

On sets where $v_R = m_{2,R} - \mu_R^2 > 0$, the first-order expansion is

$$\widehat{\text{SR}}_R - \text{SR}_R = d'_R(\hat{\theta}_R - \theta_R) + o_p(T_R^{-1/2}), \quad \theta_R = \mathbb{E}[G_t].$$

With long-run covariance $\Omega_R = \Gamma_0^R + \sum_{k \geq 1} (\Gamma_k^R + \Gamma_k^{R'})$,

$$\text{Var}_{LR}(\widehat{\text{SR}}_R) = T_R^{-1} d'_R \Omega_R d_R + o(T_R^{-1}).$$

The row-pooled IID calculation applies the same delta method to $\bar{n}T_R$ row observations $H_{t,i} = (Y_{t,i}, Y_{t,i}^2)'$:

$$\text{Var}_{IID, \text{row}}(\widehat{\text{SR}}_{\text{row}}) = (\bar{n}T_R)^{-1} d'_Y \Psi_Y d_Y + o((\bar{n}T_R)^{-1}).$$

Taking the ratio gives the Sharpe UVIF:

$$\text{UVIF}_{\text{SR}} = \frac{\bar{n} d'_R \Omega_R d_R}{d'_Y \Psi_Y d_Y} = \frac{\bar{n} d'_R \Gamma_0^R d_R}{d'_Y \Psi_Y d_Y} \times \frac{d'_R \Omega_R d_R}{d'_R \Gamma_0^R d_R}.$$

The first term is the cross-sectional component and the second term is the serial long-run factor. Componentwise,

$$d'_R \Omega_R d_R = \frac{252}{v_R^3} \left[m_{2,R}^2 \Omega_{11} - \frac{\mu_R m_{2,R}}{2} (\Omega_{12} + \Omega_{21}) + \frac{\mu_R^2}{4} \Omega_{22} \right].$$

The Ω_{22} term contains long-run covariances of squared returns and therefore brings fourth moments into Sharpe-ratio variance.

4 Capacity stress extension

The public sorted-portfolio examples in the main manuscript do not contain average daily volume or order-size information, so they do not support a capacity claim. For traded-security panels where those inputs are available, a square-root impact diagnostic can be added as an extension to the statistical claim boundary.

Proposition 1 (Asymptotic capacity frontier under square-root impact). *Suppose a traded panel has row-pooled gross mean $\bar{r}_{\text{gross}}$, row-pooled return standard deviation σ_{row} ,*

average turnover $\widehat{TO} > 0$, T trading dates, square-root impact cost $\lambda\widehat{TO}\sqrt{A/V}$, and a dependence standard-error inflation factor $\mathcal{M} \geq 1$ relative to row-pooled inference. For a one-sided level- α viability margin, any statistically certified capacity A^* must satisfy

$$A^* \leq V \left(\frac{\bar{r}_{\text{gross}} - z_\alpha \mathcal{M} \sigma_{\text{row}} / \sqrt{T}}{\lambda\widehat{TO}} \right)^2 \quad (1)$$

when the numerator is positive; otherwise no positive capacity is certified by the margin.

For a square-root impact diagnostic, the dependence-adjusted one-sided lower confidence margin for gross mean return is

$$\bar{r}_{\text{gross}} - z_\alpha \mathcal{M} \sigma_{\text{row}} / \sqrt{T},$$

where σ_{row} is the standard deviation of row-pooled returns before date aggregation or UVIF adjustment. Square-root impact subtracts $\lambda\widehat{TO}\sqrt{A/V}$. Requiring the net lower margin to be nonnegative gives

$$\lambda\widehat{TO}\sqrt{A/V} \leq \bar{r}_{\text{gross}} - z_\alpha \mathcal{M} \sigma_{\text{row}} / \sqrt{T}.$$

Rearranging yields the capacity frontier in Proposition 1. If the volatility input is already the date-level portfolio volatility, the date boundary has already embedded the cross-sectional UVIF component, so the cross-sectional part of $\mathcal{M}$ must not be multiplied in again.

5 Higher-Moment UVIF and EIR Details

For $\theta^{(4)} = (\mu, m_2, m_3, m_4)'$, define skewness and kurtosis from the central moments implied by $\theta^{(4)}$. Any adjusted Sharpe functional $h(\theta^{(4)})$ has a delta-method variance $\nabla h' \Omega^{(4)} \nabla h$, where $\Omega^{(4)}$ is the long-run covariance matrix of $(R_t, R_t^2, R_t^3, R_t^4)'$. The higher-moment UVIF is the corresponding ratio of date-level long-run variance to row-pooled IID variance. It is a diagnostic extension, not an additional empirical rejection gate.

The EIR diagnostic is

$$\text{EIR}_t = \frac{I(S_t; R_t)}{n_t \bar{I}_t}, \quad \bar{I}_t = n_t^{-1} \sum_{i=1}^{n_t} I(s_{t,i}; r_{t+1,i}).$$

Under the same equicorrelated Gaussian approximation used for the mean-return design effect,

$$\text{EIR}_t(\rho) \approx \frac{1}{1 + (n_t - 1)\rho}.$$

Table 1: Synthetic positive-control audit.

Panel	$\bar{\rho}$	Adj.	SR	HAC p^+	RW p	Perm. p^+
Synthetic control	0.202	4.58	1.744	7.67e-13	5.00e-04	9.99e-04

Table 2: Registry-defined public candidate evaluation campaign.

Candidate	status	SR	HAC p+	Boot p+	RW p	Perm p	Net SR	Pass 5%
french_momentum_deciles_daily_rank	Available	0.447	7.54e-05	2.00e-04	2.00e-04	1.000	0.447	no
french_momentum_deciles_daily_wml	Available	0.497	5.53e-06	2.00e-04	2.00e-04	1.00e-04	0.497	yes
french_size_bm_daily_dynamic_momentum	Available	0.036	0.445	0.458	0.516	0.947	-0.072	no
stooq_fixed_etf_daily_dynamic_momentum	Data unavailable							no
aqr_bab_equity_factors_daily	Available	0.741	3.08e-13	2.00e-04	2.00e-04		0.741	no
aqr_qmj_factors_daily	Available	0.536	2.26e-05	2.00e-04	2.00e-04		0.536	no
aqr_hml_devil_factors_daily	Available	0.336	0.004	0.002	0.002		0.336	no
aqr_value_momentum_everywhere_monthly	Available	2.623	1.62e-04	2.00e-04	2.00e-04		2.623	no

Thus an EIR of 0.111 means that roughly $1 - 0.111 = 0.889$, or 89 percent, of nominal row-level information is redundant under the diagnostic approximation.

9 Robustness and Registry Notes

The public registry is frozen in `code/campaign_registry.json`. It records loaders, public source metadata, threshold menus, primary thresholds, and lookback/skip parameters. Changing a source, lookback, threshold, cost assumption, or eligibility rule after seeing results creates a new researcher menu and must be reported as exploratory.

Stationarity diagnostics, holdout splits, HAC bandwidth sweeps, prewhitened HAC, fixed-fraction HAC, moving-block bootstrap, and stationary bootstrap results are secondary robustness checks. They are used to identify fragile claims, not to replace the main date-return decision boundary.
